Lecture 4: Multiparameter Models

Professor Alexander Franks

2025-01-[redacted] 22

Announcements

- Today: Chapter 3 BDA
- Next: Chapter 4 (can skim) and Chapter 5

- HW 1, due Sunday night
- Friday O.H. TBD

- Beta-Binomial
- Gam-Pois
- Uncertainty Quant.
- Post. Pred.

Post. Pred:

$$P(\tilde{y}_1, \ldots \underset{\substack{\uparrow \\ n}}{\tilde{y}_k} \mid y_1, \ldots y_n) = \int P(\tilde{y}_1, \ldots \tilde{y}_k \mid \theta)\, P(\theta \mid y_1, \ldots y_n)\, d\theta$$

Bayesian inference in the normal model

- Assume $y_1, \ldots y_n \sim N(\mu, \sigma^2)$ with σ^2 a known constant
- Let's start with a Jeffreys' (improper prior): $p(\mu) \propto \text{const}$
- What is the posterior distribution $p(\mu \mid y_1, \ldots y_n, \sigma^2)$?

Jeffreys: $\sqrt{I(\mu)} \propto \frac{n}{\sigma^2}$ ("const")

(improper prior)

$$P(\mu \mid y_1, \ldots y_n, \sigma^2) \propto e^{-\frac{\sum (y_i - \mu)^2}{2\sigma^2}} \times \text{const}$$

$$L(\mu) \times P(\mu)$$

$$\propto e^{\frac{-n\mu^2 - 2\sum y_i \mu + \text{const}\ 1/n}{2\sigma^2}\ 1/n}$$

$$\propto e^{-\frac{\mu^2 - 2\bar{y}\mu}{2\sigma^2/n}}$$

$$\propto e^{\frac{(\mu - \bar{y})^2}{2\sigma^2/n}}$$

$$\Longrightarrow P(\mu \mid \ldots) \sim N\left(\bar{y}, \frac{\sigma^2}{n}\right)$$

$$\hat{\mu}_{MLE} = \bar{Y} \sim N(\mu, \sigma^2/n)$$

$$\sqrt{\sigma^2/n}\,(\mu - \bar{y}) \sim N(0, 1)$$

Bayesian inference in the normal model

- Assume $y_1, \ldots y_n \sim N(\mu, \sigma^2)$ with σ^2 a known constant
- The normal prior distribution is conjugate for μ in the normal sampling model
- Sampling distribution, prior distribution and posterior distribution are all normal.
- Assume the prior is $p(\mu) \sim N(\mu_0, \sigma^2/\kappa_0)$
- What are the parameters of the posterior $p(\mu \mid y_1, \ldots y_n, \sigma^2)$?

$$P(\mu \mid y_1, \ldots y_n, \sigma^2) \propto L(\mu)\, P(\mu)$$

$$\propto e^{-\frac{(\mu-\bar{y})^2}{2\sigma^2/n}} \times e^{-\frac{(\mu-\mu_0)^2}{2\sigma^2/\kappa_0}}$$

$$\propto \exp\left[-\frac{1}{2}\left[\frac{n+\kappa_0}{\sigma^2}\mu^2 - 2\left(\frac{n\bar{y}}{\sigma^2} + \frac{\kappa_0}{\sigma^2}\mu_0\right)\mu + \ldots\right]\right]$$

$$\propto \exp\left[-\frac{1}{2}\underbrace{\left(\frac{n+\kappa_0}{\sigma^2}\right)}_{\text{Precision}}\left(\mu - \frac{\frac{n\bar{y}}{\sigma^2} + \frac{\kappa_0}{\sigma^2}\mu_0}{\frac{n+\kappa_0}{\sigma^2}}\right)^2 + \text{const}\right]$$

$$\sim N\left(w\bar{y} + (1-w)\mu_0, \frac{\sigma^2}{n+\kappa_0}\right)$$

$$w = \frac{n/\sigma^2}{(n+\kappa_0)/\sigma^2} = \boxed{\frac{n}{n+\kappa_0}}$$

A conjugate prior for the normal likelihood

- The normal distribution is conjugate for the normal likelihood
  - Often called the "normal-normal model"
- $Y_i \sim N(\mu, \sigma^2)$ and $\mu \sim N(\mu_0, \sigma^2/\kappa_0)$ implies that the posterior distribution $p(\mu \mid y)$ is also normally distributed:

$$\mu \mid Y \sim N(\mu_n, \tau_n^2)$$

where $\mu_n = \frac{\frac{\kappa_0}{\sigma^2}\mu_0 + \frac{n}{\sigma^2}\overline{y}}{\frac{\kappa_0}{\sigma^2} + \frac{n}{\sigma^2}}$ and $\tau_n^2 = \frac{1}{\frac{\kappa_0}{\sigma^2} + \frac{n}{\sigma^2}}$

The posterior mean and pseudo-counts

Fisher-weighting.

$$\mu_n = \frac{\frac{1}{\tau^2}}{\frac{1}{\tau^2} + \frac{n}{\sigma^2}}\mu_0 + \frac{\frac{n}{\sigma^2}}{\frac{1}{\tau^2} + \frac{n}{\sigma^2}}\overline{y}$$

$$= (1 - w)\mu_0 + w\bar{y}$$

where $w = \frac{\frac{n}{\sigma^2}}{\frac{1}{\tau^2} + \frac{n}{\sigma^2}}$

Reparam: $\tau^2 = \frac{\sigma^2}{\kappa_0}$

$w = n / (n + \kappa_0)$

$y_i \sim N(\mu, \sigma_i^2)$, σ_i^2 is known, can differ by i.

$$\hat{\mu}_{MLE} = \sum_{i=1}^{n} \frac{1/\sigma_i^2}{\sum 1/\sigma_j^2} y_i$$

Known mean, unknown variance

- Assume we have n mean-zero normal observations with variance σ^2
- Define $d_i = (y_i - \mu)$ for notational convenience
- What is $p(\sigma^2 \mid \mu, d_1, \ldots d_n)$?

$$L\left(\overset{\theta}{\sigma^2}\right) \propto \left(\overset{\theta}{\sigma^2}\right)^{-n/2} \exp\left\{-\sum_{i=1}^{n} d_i^2 / \left(2\overset{\theta}{\sigma^2}\right)\right\}, \ \sigma^2 > 0$$

Jeffreys Prior: $P(\sigma^2) \propto 1/\sigma^2$

$$\int_0^\infty \frac{1}{\sigma^2}\, d\sigma^2 < \infty \quad , \quad \int_0^\infty \frac{1}{\sigma}\, d\sigma$$

analogous $\int_0^\infty \frac{1}{x}\, dx = \infty$

<u>Careful!</u>

$$P(\sigma) \propto \frac{1}{\sigma} \quad \text{(Jeffreys)}$$

$$P(\sigma^2) \propto \frac{1}{\sigma^2}$$

<u>Improper</u>

Known mean, unknown variance

- Assume we have n mean-zero normal observations with variance σ^2
- Jeffreys prior $p(\sigma^2) \propto \frac{1}{\sigma^2}$ (careful!)
- The posterior:
  $p(\sigma^2 \mid y) \propto \left(\sigma^2\right)^{-n/2-2} \exp\left\{-\sum_{i=1}^n d_i^2 / \left(2\sigma^2\right)\right\}$
- This distribution called an *inverse-Gamma* distribution.
  - If $X \sim \mathrm{Gamma}(a, b)$ then $\frac{1}{X} \sim \mathrm{Inv\text{-}Gamma}(a, b)$.

$$p(\sigma^2 \mid y_1, \ldots y_n, \mu) \sim IG\left(n/2, \frac{\sum d_i^2}{2}\right)$$

$\Longleftrightarrow$ $\underline{\text{Scaled Inv-}\chi^2}\left(n, \frac{\sum d_i^2}{n}\right)$

sample size.

sample var.

$z_i \overset{iid}{\sim} N(0,1)$

$\sum^{K} z_i^2 \sim \chi^2_K$, $\sigma^2 \chi^2_K$ is a scaled χ^2

$1/\sigma^2\chi^2_K$

$\chi^2_K \equiv \text{Gam}\left(\frac{K}{2}, 1/2\right)$

A conjugate prior distribution

- In general, the conjugate prior distribution has the form:

$$p(\sigma^2) \propto (\sigma^2)^{-k_1} e^{\frac{k_2}{\sigma^2}}$$

- Inverse-gamma: $p(y \mid a, b) = \frac{b^a}{\Gamma(a)} y^{-a-1} \exp\left(-\frac{b}{y}\right)$
  - The mean of an inverse-Gamma is b/(a-1)

$P(\mu, \sigma^2 | y_1, \ldots y_n)$?

What's the conjugate prior?

$$P(\mu, \sigma^2) = \underbrace{P(\mu | \sigma^2)}_{\text{Done, nice}} \boxed{P(\sigma^2)}$$

$\neq P(\sigma^2 | \mu)$

Joint inference for the mean and variance

In the normal model we typically factorize the prior distribution $p(\mu, \sigma^2) = p(\mu \mid \sigma^2)p(\sigma^2)$.

Specifically:

same as before.

$$\sigma^2 \sim Inv - Gamma(\nu_0/2, \nu_0/2\sigma_0^2)$$

$$\mu|\sigma^2 \sim \text{ normal } \left(\mu_0, \sigma^2/\kappa_0\right)$$

$$Y_1, \ldots, Y_n|\mu, \sigma \sim \text{ i.i.d. normal } \left(\mu, \sigma^2\right)$$

Mean

$\approx \sigma_0^2$

- ν_0 is interpreted as the prior sample size
- σ_0^2 is a prior sample variance

$$P(\mu \mid \sigma^2, y_1, \ldots y_n)\, P(\sigma^2 \mid y_1, \ldots y_n)$$

Normal — Inverse-Gam.

$$= P(\mu, \sigma^2 \mid y_1, \ldots y_n)$$

Joint inference for the mean and variance

- We write down $p(\mu, \sigma \mid y_1, \ldots y_n) \propto L(\mu, \sigma) p(\mu, \sigma)$. Now what?
- Estimands of potential interest:
  - $E[\mu \mid y_1, \ldots y_n]$ Posterior Mean of μ,
  - $E[\sigma \mid y_1, \ldots y_n]$ // of σ
  - $E[\sigma/\mu| \mid y_1, \ldots y_n]$ (coefficient of variation)

// of CV.

- $Pr(|\mu| > 2\sigma \mid y_1, \ldots y_n)$ ...

Posterior inference for arbitrary functions

Scalar - Scalar

Method of transformations

1. Find the inverse, $\theta = g^{-1}(\gamma) = \frac{e^{\gamma}}{1+e^{\gamma}}$

2. Compute $\frac{dg^{-1}(\gamma)}{d\gamma}$

3. Find

$$p_{\gamma}(\gamma \mid y_1, \ldots y_n) = \left| \frac{dg^{-1}(\gamma)}{d\gamma} \right| \times p_{\theta}(g^{-1}(\gamma) \mid y_1, \ldots y_n)$$

Posterior inference for arbitrary functions

$\theta = (\mu, \sigma^2)$

$g(\theta) = \frac{\sigma}{\mu} = \gamma$

For any $\gamma = g(\theta)$ we have

$$E(g(\theta)|y) = \int g(\theta)p(\theta|y)d\theta$$

Examples:

- $E[\gamma \mid y] = \int \log(\frac{\theta}{1-\theta})p(\theta \mid y)d\theta$
- $Pr(\theta \in R \mid y) = E(I\,[\theta \in R]|y)$

$$\int g(\theta)p_\theta(\theta \mid y_1, \ldots y_n)d\theta = \int \gamma p_\gamma(\gamma \mid y_1, \ldots y_n)d\gamma$$

Law of the Unconscious Statstician

LE CASINO
CASINO MONTE-CARLO
CASINO NIGHT
À CIEL OUVERT
ROCK

Monte Carlo Method

θ_s iid $\sim P(\theta|y)$

Want $E[g(\theta)|y_1,\ldots,y_n]$

- $\overline{\theta} = \sum_{s=1}^{S} \theta^{(s)}/S \xrightarrow{\text{LLN}} \mathrm{E}[\theta|y_1,\ldots,y_n]$
- $\sum_{s=1}^{S} \left(\theta^{(s)} - \overline{\theta}\right)^2/(S-1) \xrightarrow{\text{LLN}} \mathrm{Var}[\theta|y_1,\ldots,y_n]$
- $\#\left(\theta^{(s)} \leq c\right)/S \to \Pr(\theta \leq c|y_1,\ldots,y_n)$
- the α-percentile of $\left\{\theta^{(1)},\ldots,\theta^{(S)}\right\} \to \theta_\alpha$

Almost sure convergence due to the SLLN

Monte Carlo Error

$E[g(\theta) \mid y_1, \dots y_n]$? $\theta_s \overset{iid}{\sim} p(\theta \mid y)$

$$\frac{\sum g(\theta_s)}{S} \xrightarrow[\text{CLT}]{d} N\left(E[g(\theta) \mid y_1, \dots y_n], \frac{Var(g(\theta) \mid y_1, \dots y_n)}{S}\right)$$

M.C. error decreases like $1/S$.

MCMC, "Markov Chain" MC

Back to the normal model

Announcements

- HW 2 out, due in 1 week
- Start Ch. 5 of BDA3

Hierarchical

Example: midge wing length

- Modeling wing length of different specifies of midge (small, two-winged flies)

$E[\mu] = 1.9$

- From prior studies: mean wing length close to 1.9mm.
- Prior mean for μ is $\mu_0 = 1.9$ and Jeffreys prior for σ^2.
- Prior sample sizes: choose $\kappa_0 = 1$
- $(\bar{y}, s^2) = (1.804, 0.0169)$ are the sufficient statistics

$\mu \sim N(1.9, \frac{\sigma^2}{1})$

weakly informative.

$p(\sigma^2) \propto 1/\sigma^2$ $\quad > \quad P(\mu, \sigma^2) = P(\mu|\sigma^2)P(\sigma^2)$

Working with the log posterior

- As always, we will write down $p(\theta \mid y) \propto p(y \mid \theta)p(\theta)$
- In code, we always work with the **log-posterior** for numerical reasons
  - Mathematically it makes no difference, but computationally it is important
  - $L(\theta) \propto \prod p(y_i \mid \theta)$ is very small for moderate sample size (underflow)
  - $\ell(\theta) = \sum_{i=}^{n} log(p(y_i \mid \theta))$ is numerically stable
- Monte Carlo methods ~~only~~ require that we can evaluate the log posterior

Grid approximation

```r
log_normal_posterior <- Vectorize(function(mu, sigma) {

  ### log likelihood
  sum(dnorm(y, mu, sigma, log=TRUE)) +
  ## plus log prior
  dnorm(mu, mu0, sigma/sqrt(k0), log=TRUE) +
  -2*log(sigma)

})

post_grid <- as_tibble(
  expand.grid(seq(1.6, 2.0, by=0.001),
              seq(0.01, 0.25, by=0.001)))
colnames(post_grid) <- c("mu", "s")
```

$\log P(\sigma^2)$

$\log P(\mu|\sigma^2)$

evaluate $\ell(\theta)$

$$L(\mu,\sigma^2) = \prod^{n} \frac{1}{\sqrt{2\pi}\,\sigma} e^{-(y_i-\mu)^2}$$

$$\ell(\mu,\sigma^2) = \sum \ldots$$

  geom_vline(xintercept=ybar, linetype="dashed")
```

$P(\mu, 1/\sigma^2 \mid y_1, \ldots y_n)$

Sampling from the joint posterior

- Contour and raster plots allow us to visualize the posterior (in two dimensions)
  - Grid sampling approximates posterior samples
  - Need to know approximately where the high posterior density is (not easy)
- When we have more than 2 parameters visualization isn't feasible
- How do we summarize the posterior?
  - e.g. posterior means, posterior probabilities, intervals, etc..

Visualizing Posterior Samples

```r
post_grid %>%
  mutate(density = exp(log_normal_posterior(mu, sqrt(1/prec)))) %>%
  mutate(density = density / sum(density)) -> post_grid

sample_indices <- sample(1:nrow(post_grid), size=10000, replace=TRUE, prob=

post_grid[sample_indices, ] %>%
  mutate(prec = 1/s^2) %>%
  ggplot() +
  geom_point(aes(x=mu, y=prec)) +
  theme_bw(base_size=16)
```

Prob = density

MC

$P(\mu > 1.9 \mid \ldots)$

$\frac{1}{\sigma^2} > 100$

Visualizing Posterior Samples

```
post_grid %>%
  mutate(density = exp(log_normal_posterior(mu, sqrt(1/prec)))) %>%
  mutate(density = density / sum(density)) -> post_grid

sample_indices <- sample(1:nrow(post_grid), size=10000, replace=TRUE, prob=

post_grid[sample_indices, ] %>%
  mutate(prec = 1/s^2) %>%
  ggplot() +
  ggdensity::geom_hdr(aes(x=mu, y=prec)) +
  theme_bw(base_size=16)
```

Visualizing Posterior Samples

HPD

Direct Sampling

Relies on Conjugacy

- $p(\mu, \sigma^2 \mid y) = p(\mu \mid \sigma^2, y)p(\sigma^2 \mid y)$
- Need to know how to sample from $p(\sigma^2 \mid y) = \int p(\mu, \sigma^2 \mid y) d\mu$ and $p(\mu \mid \sigma^2, y)$
- With the proposed conjugate priors, this integral is tractable

$$N\left(w\bar{y} + (1-w)\mu_0, \frac{\sigma^2}{n+k_0}\right)$$

$$w = \frac{n}{n+k_0}$$

for s

1. $\sigma_s^2 \sim P(\sigma^2 / y)$

2. $\mu_s \sim P(\mu \mid \sigma^2, y)$

Direct Sampling

- $p(\mu, \sigma^2 \mid y) = p(\mu \mid \sigma^2, y) p(\sigma^2 \mid y)$
- Need to know how to sample from $p(\sigma^2 \mid y) = \int p(\mu, \sigma^2 \mid y) d\mu$ and $p(\mu \mid \sigma^2, y)$
- With the proposed conjugate priors, this integral is tractable

$$\left\{1/\sigma^2 \mid y_1, \ldots, y_n\right\} \sim \text{gamma}\left(\nu_n/2, \nu_n \sigma_n^2/2\right), \text{ where}$$

$$\nu_n = \nu_0 + n$$

$$\sigma_n^2 = \frac{1}{\nu_n}\left[\nu_0 \sigma_0^2 + (n-1)s^2 + \frac{\kappa_0 n}{\kappa_n}(\bar{y} - \mu_0\right.$$

Direct Sampling

```r
## posterior parameters
kn <- k0 + n
nun <- nu0 + n
mun <- (k0 * mu0 + n * ybar) / kn
s2n <- (nu0*s20 + (n-1)*s2  + k0*n / kn * (ybar - mu0)^2) / nun

nsamps <- 10000
prec_samps <- rgamma(nsamps, nun/2, nun*s2n/2)
mu_samps <- rnorm(nsamps, mun, sqrt((1/prec_samps) / kn))

tibble(mu=mu_samps, prec=prec_samps) %>%
  ggplot() +
  geom_point(aes(x=mu, y=prec)) +
  #ggdensity::geom_hdr(aes(x=mu, y=prec)) +
  theme_bw(base_size=16)
```

1. $1/\sigma^2$
2.

Direct Sampling

Bayes Estimators

(Decision Theory)

Why the posterior mean?

- Often times we need to make a "decision" by providing a single estimate
- The posterior provides a full distribution over θ, which can be summarized in infinitely many ways
- Specify a *loss function* which describes the cost of estimating $\hat{\theta}$ when the truth is θ

Posterior Mean
has nice form,
w/ conj. priors.

Bayes Estimators

- The *loss function*: $L(\hat{\theta}, \theta)$
  - Squared error: $L(\hat{\theta}, \theta) = (\hat{\theta} - \theta)^2$
  - Absolute error: $L(\hat{\theta}, \theta) = |\hat{\theta} - \theta|$
- The *Bayes risk* is the posterior expected loss: $E_{\theta|y}[L(\hat{\theta}, \theta)]$

Average over post. unc. of θ.

- Summarize the posterior by minimizing the Bayes risk.
- An estimator $\hat{\theta}$ is said to be a Bayes estimator if it minimizes the Bayes risk among all estimators.

Examples Squared error loss

$$\min_{\hat{\theta}} E_{\theta|y}(\hat{\theta}-\theta)^2 = \min_{\hat{\theta}} \int (\hat{\theta}-\theta)^2 p(\theta \mid y) d\theta$$

DUTHIS

$$\frac{d}{d\hat{\theta}} \int (\hat{\theta}-\theta)^2 p(\theta|y)\, d\theta =$$

$$\int 2(\hat{\theta}-\theta) p(\theta|y) = 0$$

$$\int \cancel{2}\hat{\theta}\, p(\theta|y)\, d\theta = \int \cancel{2}\theta\, p(\theta|y)\, d\theta$$

$$\hat{\theta} \underbrace{\int P(\theta|y)\,d\theta}_{1} = \int \theta\, P(\theta|y)\,d\theta = E[\theta|y]$$

The Bias-Variance Tradeoff

- The prior distribution (usually) makes your estimator biased…
- But the prior distribution also (usually) reduces the variance!
- Bayes estimators are (usually) consistent
- Example: compute the frequentist mean and variance of the posterior mean.

Example: IQ scores

μ?

- Scoring on IQ tests is designed to yield a N(100, 15) distribution for the general population
- We observe IQ scores for a sample of n individuals from a particular town and estimate μ, the town-specific IQ score
- If we lacked knowledge about the town, a natural choice would be $\mu_0 = 100$
- Suppose the true parameters for this town are $\mu = 112$ and $\sigma = 13$
  - The town is smarter on average than the general population

$$y_1, \dots y_n \sim N(\mu, \sigma^2)$$

$$E[\mu \mid y_1, \dots y_n] = w\bar{y} + (1-w)\mu_0$$

(estimate!)

Estimator: $w\bar{Y} + (1-w)\mu_0 = \hat{\mu}$

$$E[(\hat{\mu} - \mu)^2] = Var(\hat{\mu}) + Bias(\hat{\mu})^2$$

MLE

$$Var(\hat{\mu}_{MLE}) = Var(\bar{Y}) = \frac{\sigma^2}{n}$$

$$E[\hat{\mu}_{MLE}] = E[\bar{Y}] = \mu, \quad Bias = 0$$

$$MSE_{MLE} = \sigma^2/n$$

PM

$$Var(\hat{\mu}_{PM}) = Var(w\bar{Y} + (1-w)\mu_0)$$

$$= w^2 \sigma^2/n$$

$$E(\hat{\mu}_{PM}) = E[w\bar{Y} + (1-w)\mu_0]$$

$$= w\mu + (1-w)\mu_0$$

$$\text{Bias}(\hat{\mu}_{PM}) = w\mu + (1-w)\mu_0 - \mu$$
$$= (1-w)(\mu_0 - \mu)$$

$$\text{MSE } \hat{\mu}_{PM} = \frac{w^2\sigma^2}{n} + (1-w)^2(\mu - \mu_0)^2$$

$$\text{MSE P.M} \overset{??}{\underset{<}{>}} \text{MSE MLE}$$

$$\frac{w^2\sigma^2}{n} + (1-w)^2(\mu - \mu_0)^2 \quad ?? \quad \sigma^2/n$$

Example: IQ scores

- What is the mean squared error of the MLE? MSE of the posterior mean?

$\sigma = 13$ $\mu_0 = 100$

$\mu = 112$

- $\text{MSE}\left[\hat{\mu}_{MLE}\right] = \text{Var}\left[\hat{\mu}_{MLE}\right] = \frac{\sigma^2}{n} = \frac{169}{n}$

- $\text{MSE}\left[\hat{\mu}_{PM}|\theta_0\right] = w^2 \frac{169}{n} + (1-w)^2 144$

Example: IQ scores

$\mu \sim N(100, \sigma^2/\kappa_0)$

$\frac{MSE(\hat{\mu}_{PM})}{MSE(\hat{\mu}_{MLE})}$

$P(\mu \mid y_1, \ldots, y_n)$

The Multivariate Normal Distribution

$$Y_{p\times 1} = \begin{bmatrix} Y_1 \\ \vdots \\ Y_p \end{bmatrix} \sim N_p(\mu, \Sigma)$$

$$P(Y = y \mid \mu, \Sigma) = \cancel{(2\pi)^{-1/2}} \underline{|\Sigma|^{-1/2} e^{\left(-\frac{1}{2}(y-\mu)'\Sigma^{-1}(y-\mu)\right)}}$$

$$\mu \in \mathbb{R}^p$$

$\Sigma \in S_p^+$ cone of pos. def. matrices.

$(x'\Sigma x > 0 \quad \forall x)$, $\frac{p(p+1)}{2}$ free

$a'Y \sim \text{Norm}, \ \forall\, a$
conditionals are norm.

Assume $\underline{\Sigma}$ is known.

$$P(\mu \mid \Sigma, y_1, \ldots y_n) \; ??$$

$$P(\mu) \sim N_p(\mu_0, \Lambda_0)$$

$$L(\mu) \propto \prod^{n} \cancel{(2\pi)^{-1/2}} \cancel{|\Sigma|^{-1/2}} e^{-\frac{1}{2}(y_i-\mu)'\Sigma^{-1}(y_i-\mu)}$$

$$\propto \exp\left[-\frac{1}{2}\sum (y_i-\mu)'\Sigma^{-1}(y_i-\mu)\right]$$

$$\propto \exp\left[-\frac{1}{2}\mu' A \mu + \mu' b\right]$$

$$A = n\Sigma^{-1}, \quad b = n\Sigma^{-1}\bar{y}$$

$$P(\mu) \propto \exp\left[-\frac{1}{2}\mu'\Lambda_0^{-1}\mu + \mu'\Lambda_0^{-1}\mu_0\right]$$

$$p(\mu \mid y_1, \dots y_n, \Sigma) \propto \qquad \boxed{(\mu - \cdot)' \Sigma^{-1} (\mu - \cdot)}$$

$$\exp\left[\mu' A_n \mu + \mu' \underbrace{\left(b + \Lambda_0^{-1} \mu_0\right)}_{n \Sigma^{-1} \bar{y} + \Lambda_0^{-1} \mu_0}\right]$$

$$A_n = \Sigma^{-1} + \Lambda_0$$

$$\sim N(\mu_n, \Sigma_n)$$

$$\Sigma_n = \left(n \Sigma^{-1} + \Lambda_0^{-1}\right)^{-1}$$

$$\boxed{\mu_n = \left(n \Sigma^{-1} + \Lambda_0^{-1}\right)^{-1} \left(n \Sigma^{-1} \bar{y} + \Lambda_0^{-1} \mu_0\right)}$$

$$\Sigma^{-1} = 1/\sigma^2 \qquad \Lambda^{-1} = 1/\lambda \quad \Rightarrow \quad \frac{n/\sigma^2}{n/\sigma^2 + 1/\lambda} \quad \text{1d case.}$$

<u>Special Case:</u> $\boxed{\Lambda_0^{-1} = k_0 \Sigma^{-1}}$

$$\mu_n = \left(n \Sigma^{-1} + k_0 \Sigma^{-1}\right)^{-1} \left(n \Sigma^{-1} \bar{y} + k_0 \Sigma^{-1} \mu_0\right)$$

$$= \frac{1}{n+k_0} \cancel{\Sigma} \left(n \cancel{\Sigma^{-1}} \bar{y} + k_0 \cancel{\Sigma^{-1}} \mu_0 \right)$$

$$= \frac{n}{n+k_0} \bar{y} + \frac{k_0}{n+k_0} \mu_0$$

$\frac{\sigma^2}{k_0}$ in univariate case.

$$\tau^2 \Longleftrightarrow \frac{\sigma^2}{k_0}$$

$$\boxed{P(\mu) \sim N(\mu_0, \Lambda_0)}$$

Σ unknown?

$\mu = 0$.

$$\vec{y}_1, \ldots \vec{y}_n \sim N(0, \Sigma)$$

$$S_{p \times p} = YY' = \begin{pmatrix} \sum_{i=1}^{n} y_{i1}^2 & & \left(\sum_{i=1}^{n} y_{ij} y_{ik}\right) \\ & \ddots & \\ & & \sum_{i=1}^{n} y_{ip}^2 \end{pmatrix}$$

(sum of squares matrix)

$$S \sim \text{Wishart}(n, \Sigma)$$

$$E[S] = n\Sigma$$

$$\frac{YY'}{n} \xrightarrow{LLN} \Sigma$$

$$P(S) \propto |S|^{-\frac{(n-p-1)}{2}} e^{-\frac{1}{2}tr(\Sigma^{-1}S)}$$

$S \sim$ Wish

$S^{-1} \sim$ Inv-Wish.

$$\boxed{\text{IW conjugate prior for } \Sigma}$$

$$L(\Sigma) \propto |\Sigma|^{-n/2} \exp\left[-\tfrac{1}{2}\sum_{i=1}^{n} \underbrace{y_i' \Sigma^{-1} y_i}_{\text{scalar.}}\right]$$

$tr(ABC) =$
$tr(BCA)$

$$\propto |\Sigma|^{-n/2} \exp\left[-\tfrac{1}{2}\sum_{i=1}^{n} tr(\Sigma^{-1} y_i y_i')\right]$$

$$\propto |\Sigma|^{-n/2} \exp\left[-\tfrac{1}{2} tr(\Sigma^{-1} S)\right]$$

has the same form as IW.

Dirichlet-Multinomial

Metagenomics example

- Metagenomics is the study of genetic material recovered directly from environmental samples
- Map counts of genetic material to counts of microbial species
- Assume species are sampled with replacement
  - Observed sample is a multinomial distribution
- Total counts isn't meaningful (hard to control how much total sample)
- Relative counts are meaningful

Multinomial Density

- Let $\theta = (\theta_1, \theta_2, \ldots, \theta_k)$ with $\sum_i = 1^k \theta_i = 1$
- If $Y = (Y_1, \ldots, Y_K) \sim Mult(n, \theta)$, then:
  - $Y_i \sim Bin(n, \theta_i)$
  - $Y_i + Y_j \sim Bin(n, \theta_i + \theta_j)$
- What is $\hat{\theta}_{MLE}$?

Dirichlet Distribution
